

Toric Codes

Toric geometry studies varieties that contain an algebraic torus as a dense subset and furthermore the torus acts on the variety. The importance of these varieties, called toric varieties, is based on their correspondence with combinatorial objects, this makes the techniques to study the varieties more precise.

J.P. Hansen defined in 1998 the toric codes, algebraic geometry codes over a toric variety. A convex rational polytope is the same datum as a normal toric variety X_P and a Cartier divisor D_P . For a polytope P of dimension r we obtain the **toric code** C_P by evaluating rational functions at the $(q-1)^r$ points of the algebraic torus $T \simeq (\mathbb{F}_q^*)^r$. \mathcal{C}_P is the image of the linear evaluation map

$$\operatorname{ev} : \mathcal{L}(D_P) \to (\mathbb{F}_q)^{\#T} \\ f \longmapsto (f(t))_{t \in T}$$

The dimension of the codes is computed using cohomology theory. The minimum distance is estimated using intersection theory or by a multivariate generalization of Vandermonde determinants.

Toric codes have been extended to **Generalized Toric Codes**

• $U \subset H = \{0, \dots, q-2\} \times \dots \times \{0, \dots, q-2\}, T = (\mathbb{F}_q^*)^r$ • $\mathbb{F}_q[U] \subset \mathbb{F}_q[Y_1, \cdots, Y_r]$ the \mathbb{F}_q -algebra generated by

$$\{Y^u = Y_1^{u_1} \cdots Y_r^{u_r} \mid u = (u_1, \cdots, u_r) \in U$$

The **generalized toric code** C_U is the image of the \mathbb{F}_q -linear evaluation map

$$\operatorname{ev}: \mathbb{F}_q[U] \to \mathbb{F}_q^n$$
$$f \mapsto (f(t))_{t \in T}$$

- Generalized toric codes are *r*-D cyclic codes (or multicyclic codes).
- Their dual and their metric structure were computed and studied in [D. Ruano: On the structure of generalized toric codes, arXiv:cs.IT/0611010, 2006].
- In this new work we have studied the metric structure of linear codes and obtained similar results to those for generalized toric codes for an arbitrary linear code.

Metric Structure of Linear Codes

- $B : \mathbb{F}_q^n \times \mathbb{F}_q^n \to \mathbb{F}_q$, $B(x, y) = \sum_{i=1}^n x_i y_i$ the bilinear form used to define the dual code of a linear code.
- \mathbb{F}_{q}^{n} will be the vector space over \mathbb{F}_{q} with the non-degenerated symmetric bilinear form *B* whose associated matrix is the identity matrix.
- If \mathbb{F}_{a}^{n} is the direct sum of mutually orthogonal spaces

$$\mathbb{F}_q^n = U_1 \oplus \cdots \oplus U_r$$

then we say that \mathbb{F}_{a}^{n} is the orthogonal sum of U_{1}, \ldots, U_{r} and it is denoted by

$$\mathbb{F}_q^n = U_1 \bot \cdots \bot U_r$$

Let $H \subset \mathbb{F}_{a}^{n}$ be a two-dimensional vector subspace, it is said that H is a **hyperbolic plane** if there exist x_1 , x_2 such that they generate H and

$$B(x_1, x_1) = 0, \ B(x_2, x_2) = 0, \ B(x_1, x_2) =$$

Metric Structure of Linear Codes

Diego Ruano

ruano@mathematik.uni-kl.de - University of Kaiserslautern (Germany)

A non-singular two-dimensional vector subspa if there exist x_1, x_2 which generate E and such t

 $B(x_1, x_1) = 0, \ B(x_2, x_2) = 1, \ B(x_1, x_2) = 1$

Characteristic of \mathbb{F}_q **different from 2**

• \mathbb{F}_{a}^{n} has a geometric decomposition of type r,

 $\mathbb{F}_q^n = H_1 \bot \cdots \bot H_r \bot L_1 \bot$

where H_1, \ldots, H_r are hyperbolic planes and Lone-dimensional linear varieties.

- Each hyperbolic plane is generated by two ge $H_i = \langle x_{2i-1}, x_{2i} \rangle$, such that $B(x_{2i-1}, x_{2i-1}) = 0$, if for i = 1, ..., r.
- Each one-dimensional variety is generated by
- One has that $\{x_1, \ldots, x_n\}$ is a basis of \mathbb{F}_q^n that v decomposition.

Let M be the matrix of B in the basis of the geometry Mone has that $MM^t = J_{r,s}$

where ε_i is either 1 or a fixed non-square of \mathbb{F}_a^* . A linear code is said to be **compatible with a ge type** $J_{r,s}$ if there exists a basis $\{x_1, \ldots, x_n\}$ of \mathbb{F}_a^n decomposition, in such a way that exists $I \subset \{$ is a basis of the code.

Theorem. Let the characteristic of \mathbb{F}_q be different from the second sec compatible with at least one geometric decomposition

Characteristic of \mathbb{F}_q equal to 2

• \mathbb{F}_q^n has a geometric decomposition of type r,

 $\mathbb{F}_q^n = H_1 \bot \cdots \bot H_r \bot L_1 \bot \cdots \bot$

 $\mathbb{F}_{a}^{n} = H_{1} \bot \cdots \bot H_{r} \bot L_{1} \bot \cdots \bot L_{s}$

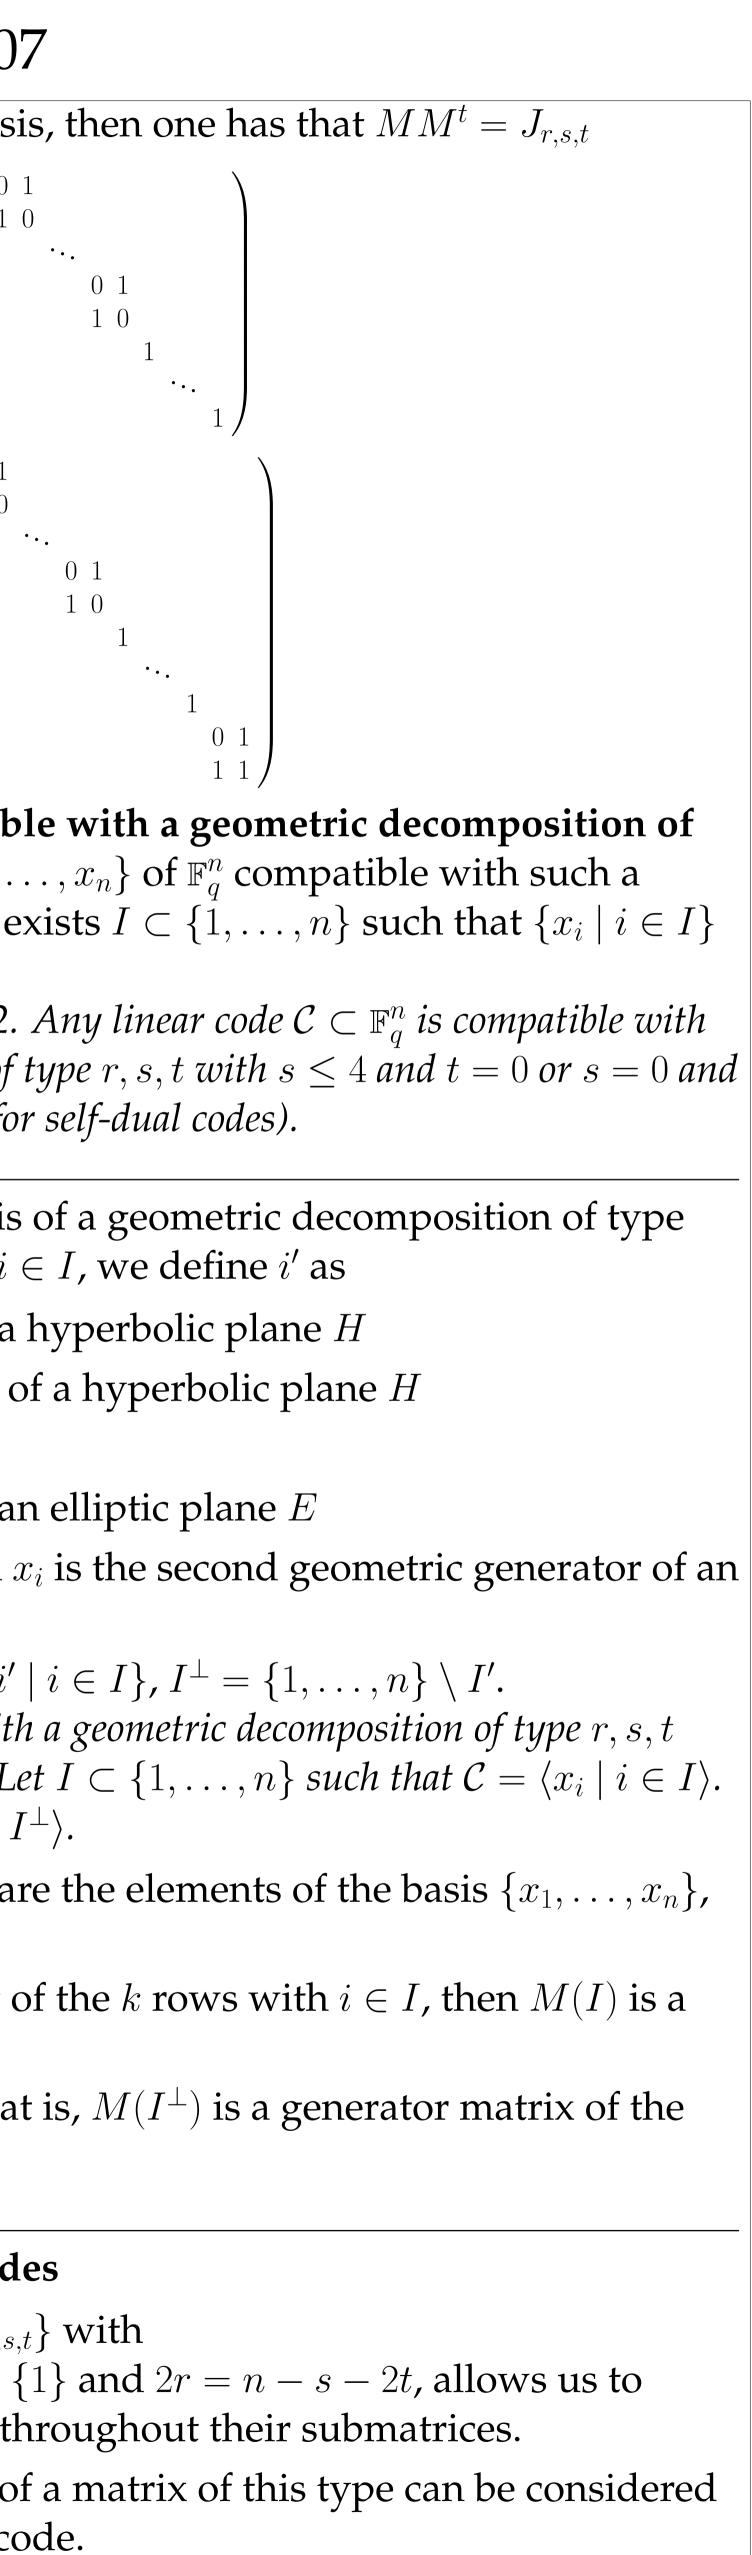

where H_1, \ldots, H_r are hyperbolic planes, L_1, \ldots one-dimensional linear varieties and E is an

- Each hyperbolic plane is generated by two ge $H_i = \langle x_{2i-1}, x_{2i} \rangle$, such that $B(x_{2i-1}, x_{2i-1}) = 0$, when i = 1, ..., r.
- Each one-dimensional variety is generated by $B(x_{2r+i}, x_{2r+i}) = 1$ when $i = 1, \dots, s$
- The elliptic plane is generated by two geomet if t = 1, such that $B(x_{n-1}, x_{n-1}) = 0$, $B(x_n, x_n)$
- One has that $\{x_1, \ldots, x_n\}$ is a basis of \mathbb{F}_a^n which geometric decomposition.
